

1. After trying different values of the variables I decided to do $\text{top}_p=0.8$. This was the most human like
2. With max_length as 45, this produced the most human like outputs. I initially tried 10, 30, 70, and 90 before this, and interestingly, the 70 input gave a less human like output than any of the others, the first time I tried it and them.
3. A short prompt became very repetitive while both medium and long were better. The medium length was the best
4. With my new model with more "neurons," the response gives more information compared with the previous thing. It goes off topic less frequently. It is more human like.
5. I learned that we should be relatively predictable so that it doesn't just go off the rails and sound like random speech all the time, but we shouldn't be entirely predictable, since that results in less creativity and doesn't sound human like. We also should use medium size sentences. We also need so many neurons in the neural network that forms the LLM since even the first had millions of neurons and even that didn't sound human like. Even the second model that I like didn't sound entirely human despite having billions of neurons, meaning that the English language and what it takes to sound human is extremely difficult to convey. This is why AI systems now use neural networks instead of grammar rules.
